

ICIMOD

EMPOWERING WOMEN IN GEOSPATIAL INFORMATION TECHNOLOGY

GIS concepts and applications

19 May 2020

Dr. Poonam Tripaathi
Training Analyst,
Geospatial Solutions, ICIMOD

INTRODUCTION TO GEOGRAPHIC INFORMATION SYSTEMS

What is GIS?

An organized integration of

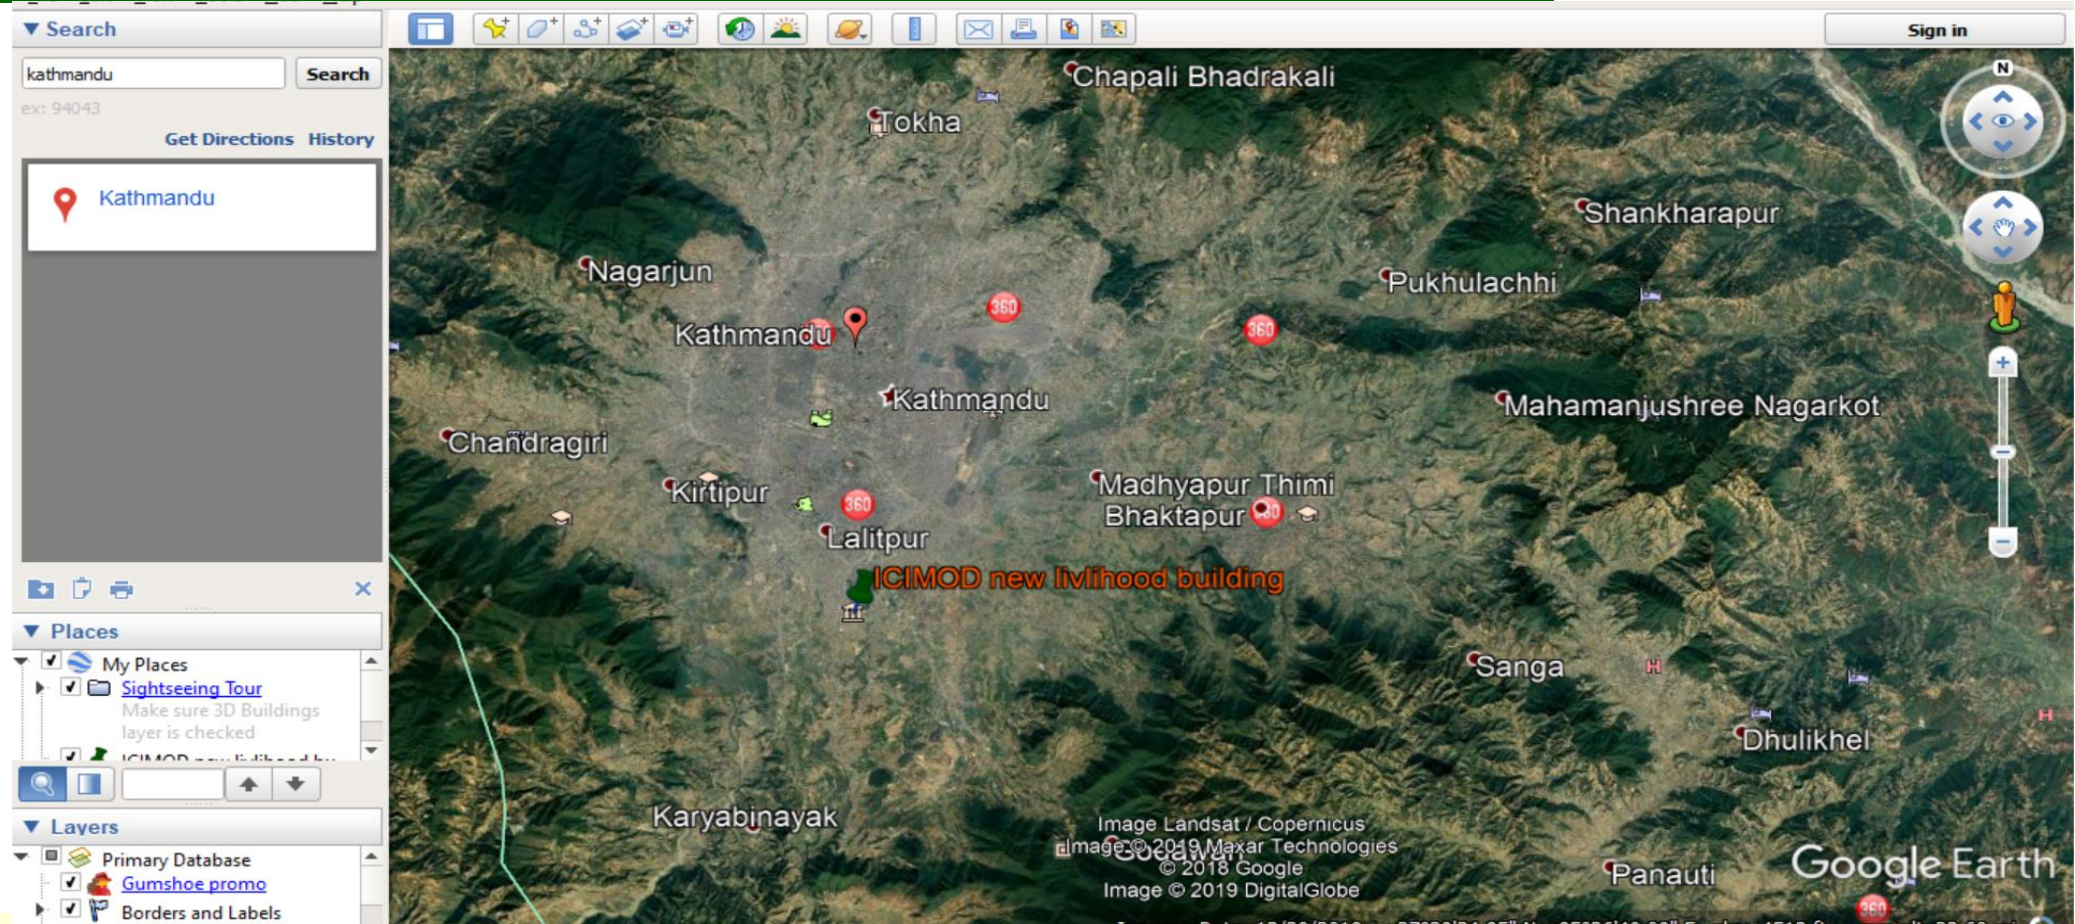

- Hardware
- Software and
- Geographic system

GEOGRAPHIC- Location

ICIMOD

FOR MOUNTAINS AND PEOPLE

Majority of data and information are associated with some location in space or referenced to the locations on the earth

INFORMATION- Attributes

7	13	13	0.65%
8	12	12	0.60%

Attributes, or the characteristics (data), can be used to symbolize and provide further insight into a given location

SYSTEM- Manipulation

A seamless operation linking the information to the geography – which requires hardware, networks, software, data, and operational procedures

Functions of GIS

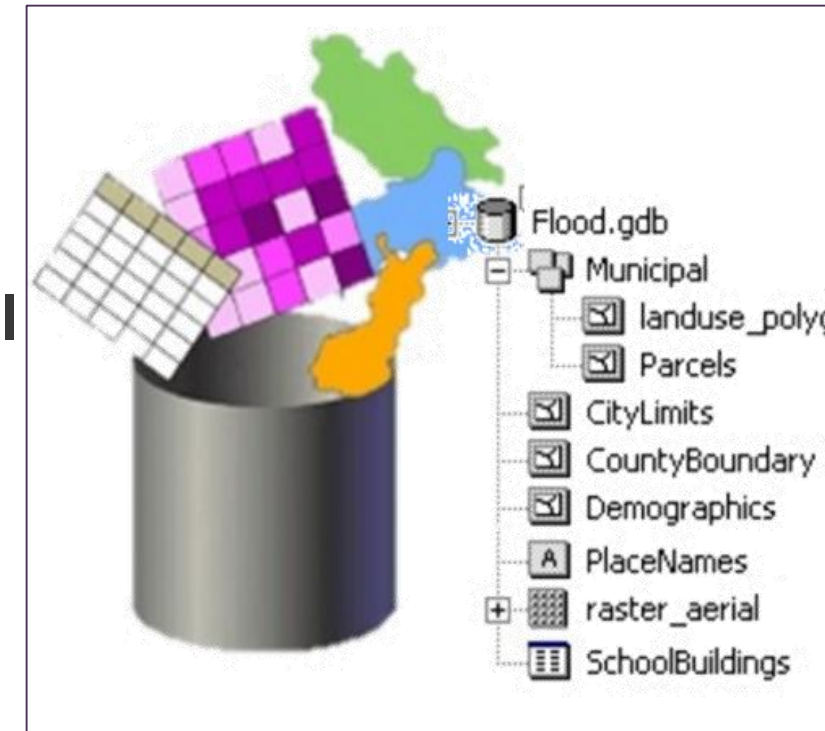

1) Data Acquisition and Preprocessing

- Digitization
- Editing
- Topology
- Projection
- Format conversion etc.

2) Database Management, Update and Retrieval

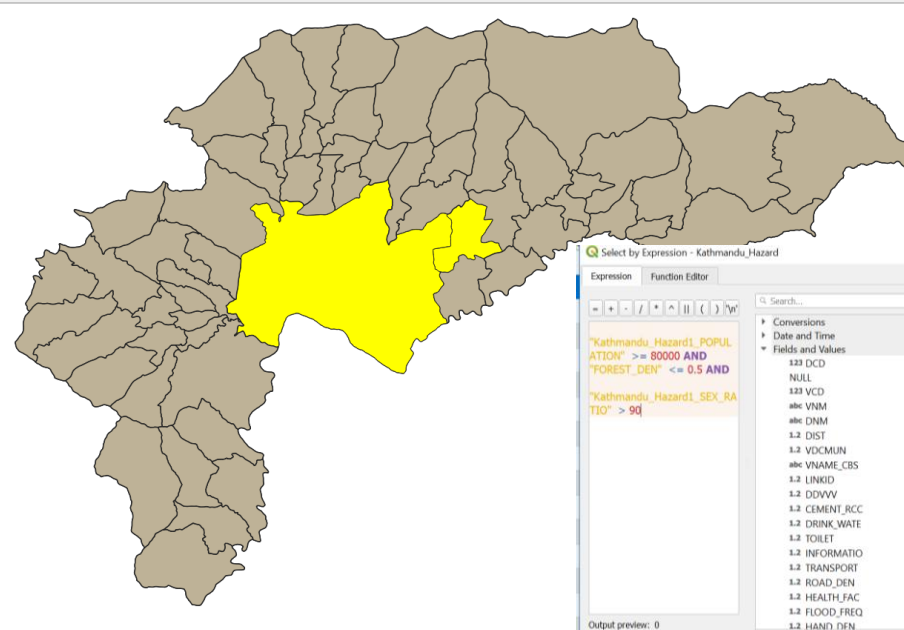

- Data retrieval
- Updation
- Maintenance
- Security and, Integration

Functions of GIS

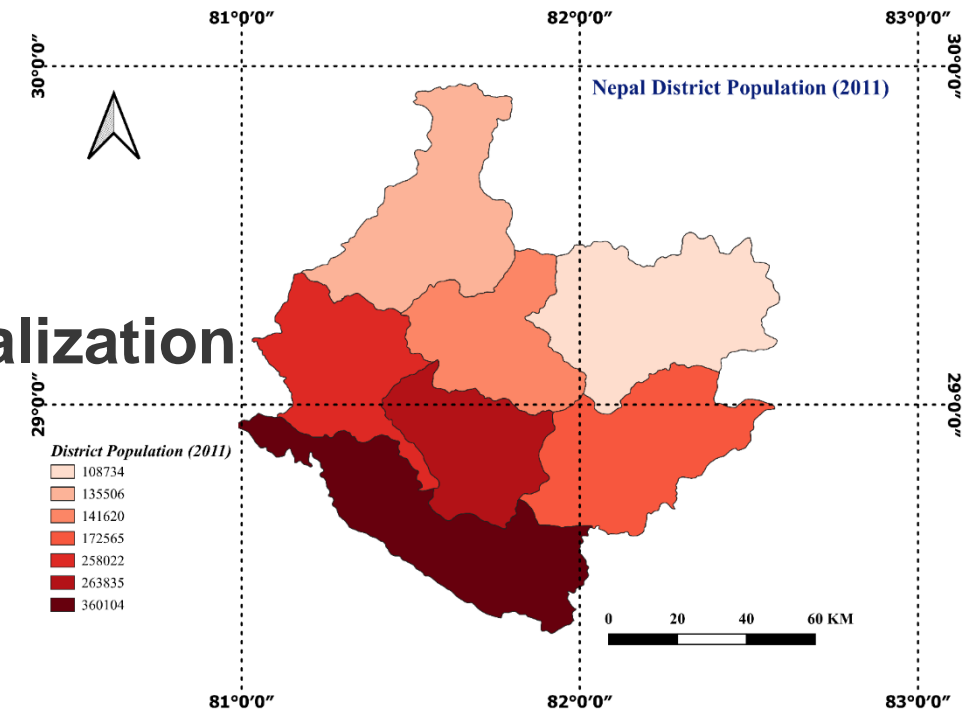

3) Spatial Modeling, Measurement and Analysis

- Hierarchical modelling
- Network modelling
- Relational modelling
- Attribute query etc.

4) Presenting Results – Graphical output and Visualization

- Scale transformation
- Generalization, Map
- Statistical representation etc.

Fundamental Data types

1) Spatial Data

Objects or elements that are present in a geographical space or horizon

- Map
- Image

2) Non-Spatial Data

Not involving Space - Describes the quantitative or qualitative characteristic of spatial features

For example, area, length & population

Spatial data can be mapped and usually stored as coordinate and topology

Fundamental Data types

Spatial Information

Non-Spatial Information

Spatial Data

Spatial Data Models

(1) Raster

- Defines space as an array of **equally sized cells** arranged in **rows and columns**. Each cell contains an **attribute value** and **location coordinates**
- The spatial resolution is determined by the **size of the cell**
- Data values for a given parameter are stored in each cell – these values may represent an elevation in meters above sea level, a land use class, a plant biomass in grams per square meter, and so forth

Spatial Data

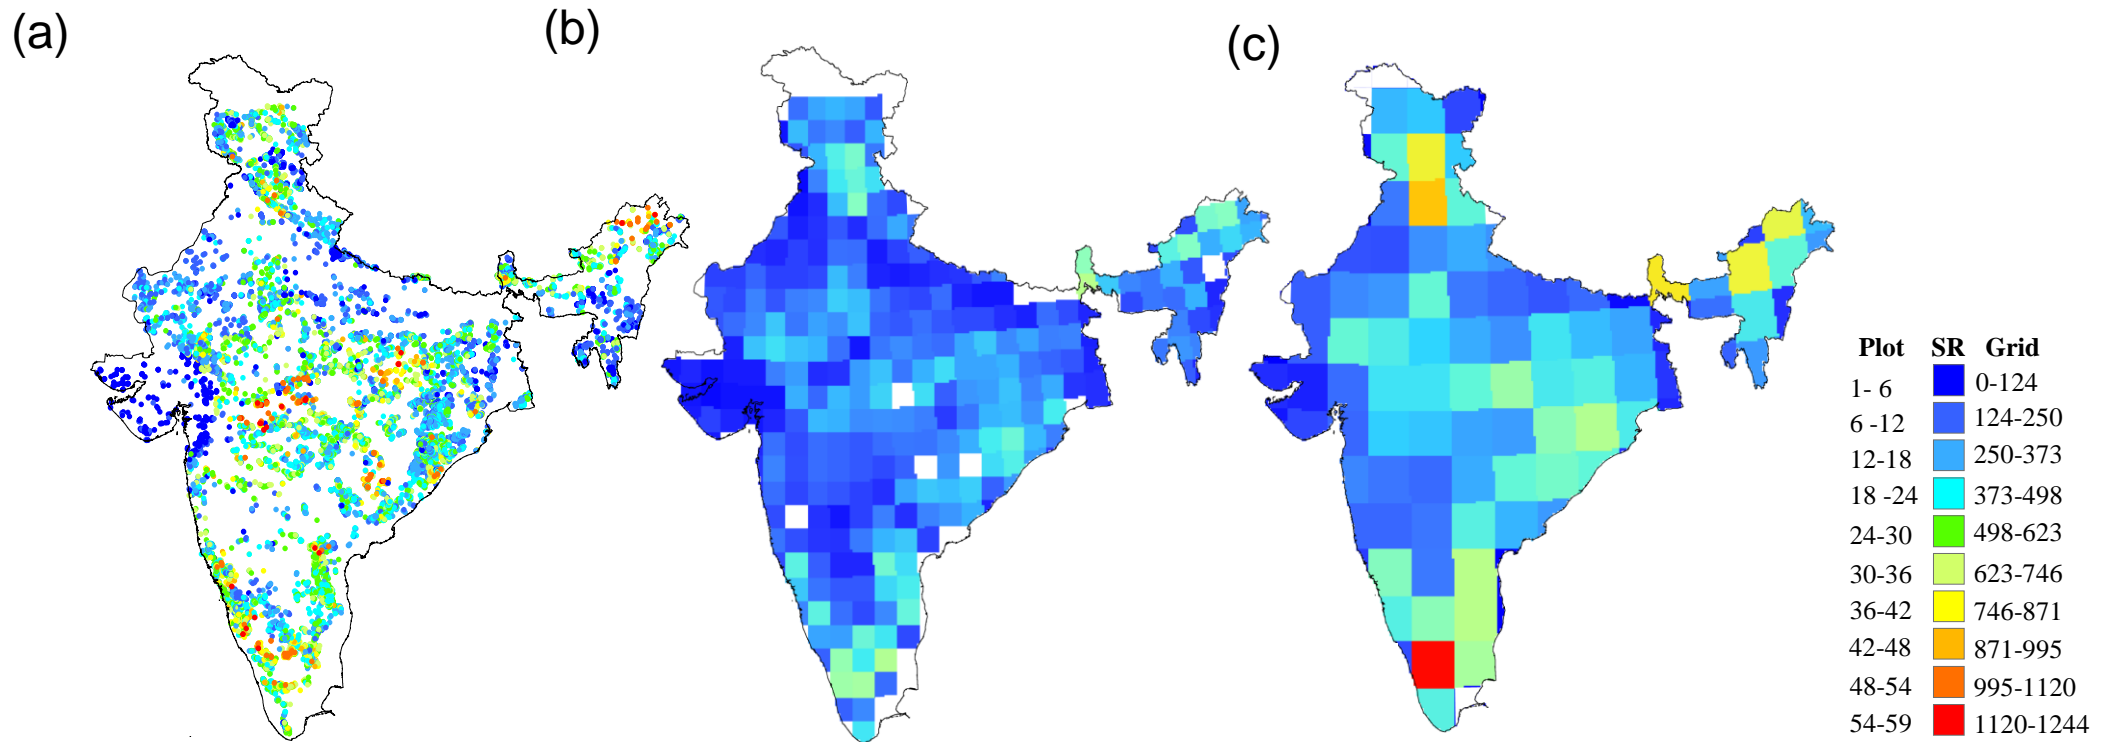

Structure of raster data model showing the matrix structure into row and column of the cells

Spatial Data

The spatial resolution is determined by the size of the cell

Spatial Data

Plant species distribution in Indian mainland
(a) plot level (0.04hac), (b) 1 degree grid, (c) 2 degree grid

Spatial Data

Two forms of raster data

1) Continuous Raster

- Numeric values ranges smoothly from one location to another
e.g. DEM, temperature etc.

2) Discrete Raster

- Relative few possible values to repeat themselves in adjacent cells.
e.g. Soil type, Land use land cover type etc.

Spatial Data

Spatial Data Models

(2) Vector

- Objects are represented as **Points**, **Lines** or **Polygon**
- The position of each object is defined by a (series of) coordinate pairs
- A point is described by a single X-Y coordinate pair and by its name or label e.g. buildings, trees etc.
- A line is described by a set of coordinate pairs and by its name and label e.g. streams, streets, sewers
- An area, also called a Polygon, is described by a set of a coordinate pairs and by its name and label, with the difference that the coordinate pairs at the beginning and the end are same .e.g. Land parcels, cities, countries, forest, rock type etc.

Point

Line

Area

Spatial Data

Topological property of vector data model

Connectivity: Information about linkages among spatial objects.

Arc node topology supported through an arc-node list. For each arc in the list there is a **from node** and a **to node**. Connected arcs are determined by common node numbers

Contiguity: Polygons share a **common arc**. Contiguity allows the vector data model to determine adjacency

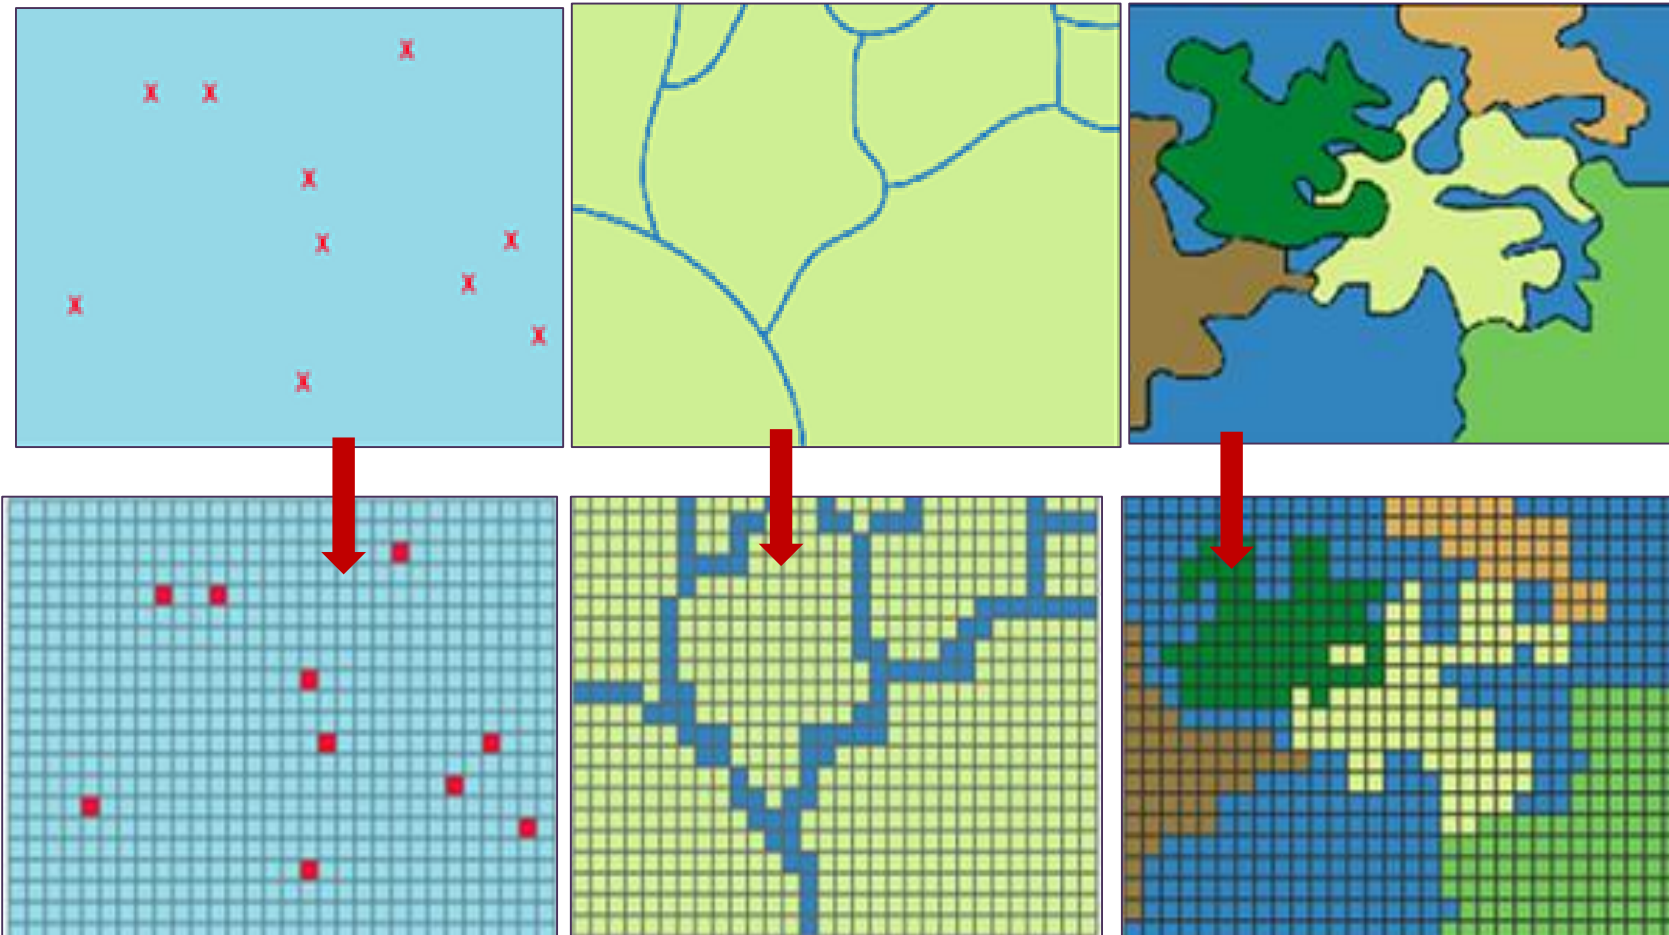

Containment: Geographic features cover distinguishable area on the surface of the earth. An area is represented by one or more boundaries defining a polygon

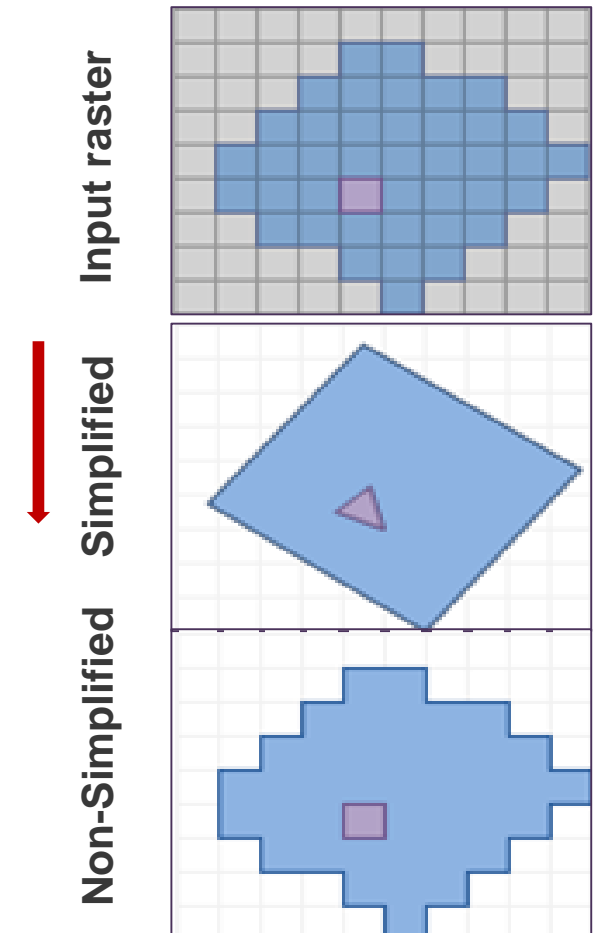

Set of rules that model the relationships between neighboring points, lines, and polygons and determines how they share geometry

Spatial Data

Conversion of vector to raster

Conversion of raster to vector

Spatial Data

FOR MOUNTAINS AND PEOPLE

		Raster	Vector	
Data structure	Advantage	Simple	Complex	Disadvantage
Overlaying		Easy and efficient	Difficult to perform	
Compatible with RS imagery		Yes	No	
High spatial variability		Efficient representation	In-efficient representation	
Programming by user		Yes	Complex	
Compact data structure	Disadvantage	No	Yes	Advantage
Efficient encoding of topology		No	Yes	
Easy editing		No	Yes	
Network analysis		In-efficient	Efficient	
Map output		Less accurate	Accurate	
Projection transformation		In-efficient	Efficient

Non-Spatial Data

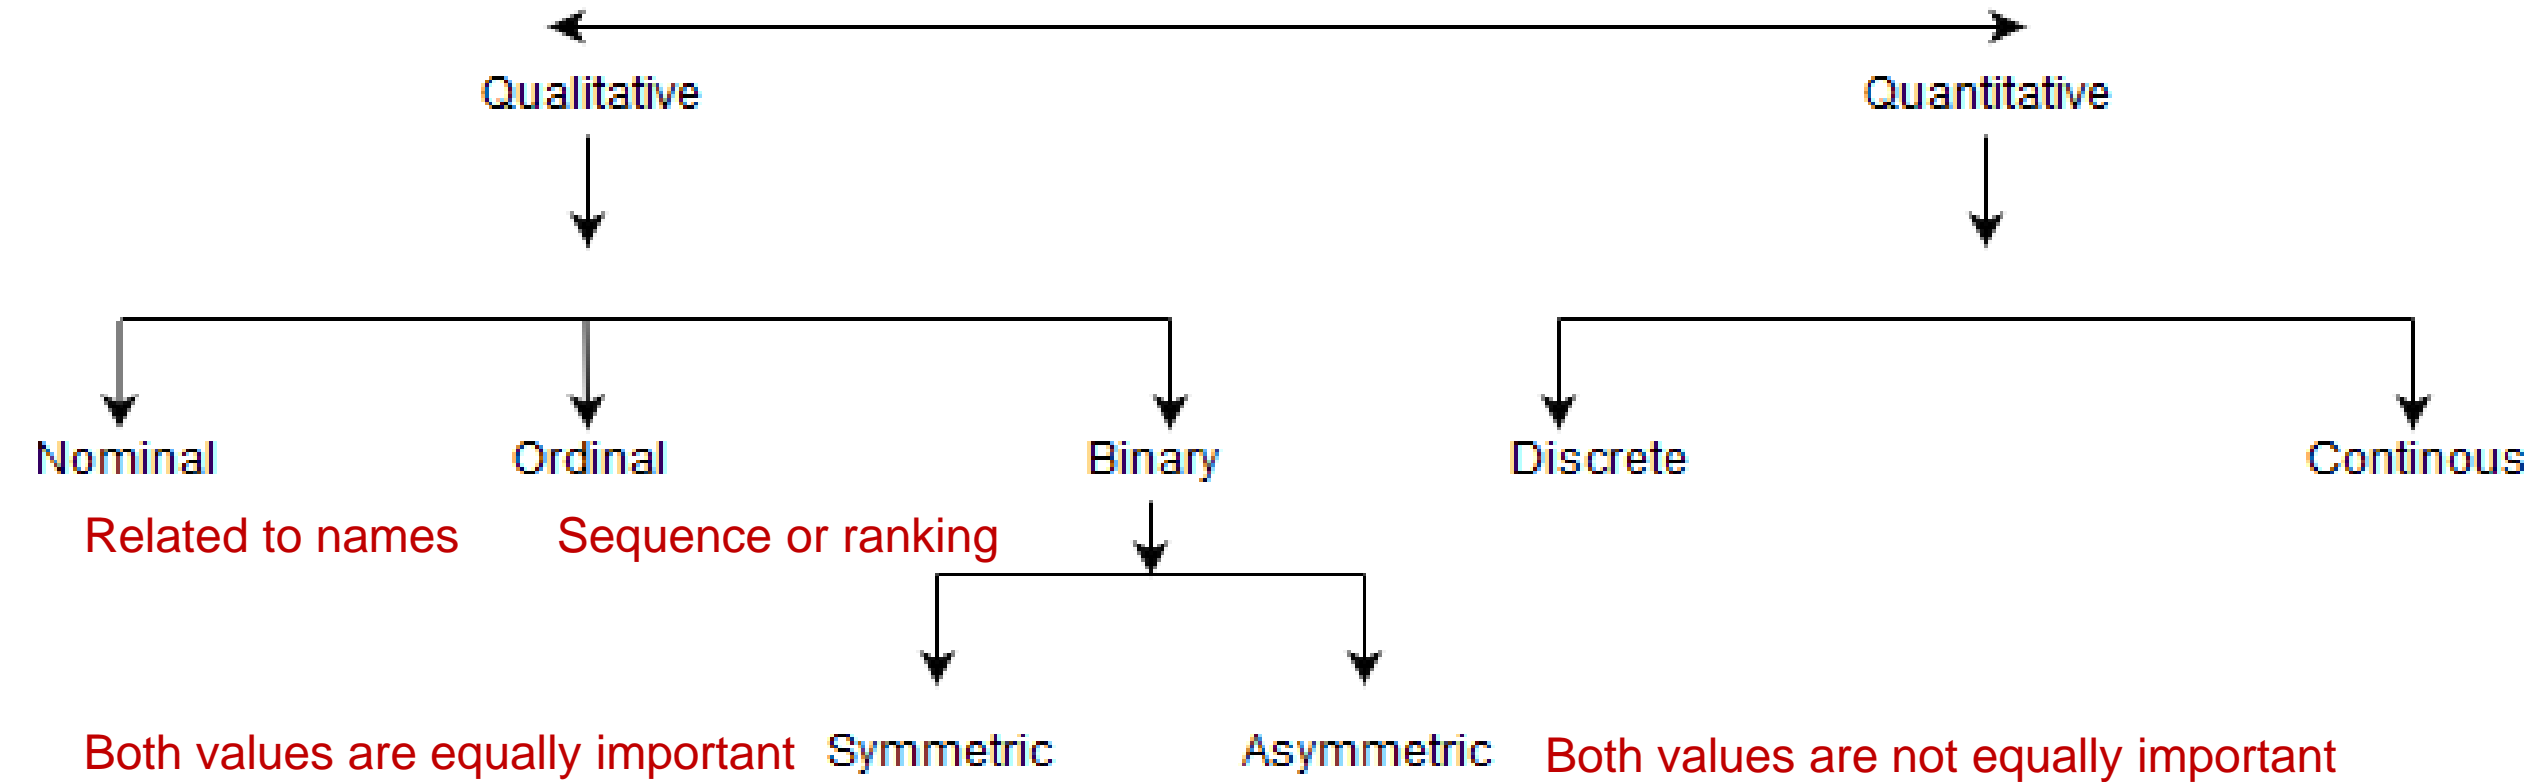

Attribute Data

- Commonly arranged in tables where a row is equivalent to one entity and a column is equivalent to one **attribute, or descriptor**, of that entity
- Typically, each row relates to a **single object** and a geospatial data model
- Usually each object will have **multiple attributes** that describe the object

Non-Spatial Data

Attribute Data Type

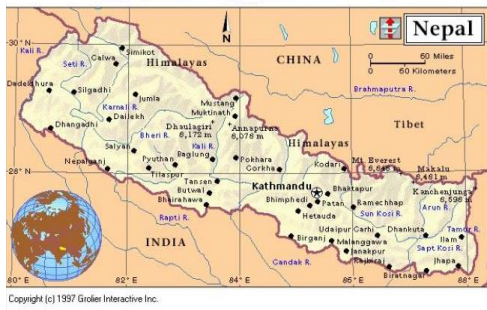

- Date:** This data type stores dates and times in the format as 'mm/dd/yyyy hh:mm:ss'

GIS data capture and update of Vector feature

FOR MOUNTAINS AND PEOPLE

Raster		Vector
Digital Remote sensing images	Primary	GPS measurements
Digital Aerial photographs		Survey measurements
Scanned Maps	Secondary	Topographic surveys
DEM from Images		Toponymy data from atlases

- LULC
- Crop types
- Census
- Biomass

GIS data capture and update of vector features

Digitization: Process of converting geographic data into vector data by tracing the features from a hardcopy, digital or a scanned image

a) Manual

(i) Tablet Digitization

- Uses hard copy maps in GIS
- Involves placing a digitizing puck (a multiple button mouse) over a location on the tablet and presses one of the buttons on the puck to record the location of the feature of interest

(ii) On-screen Digitization

User generates vector data on desktop GIS by clicking on features that defines the entity

b) Automated digitization

Scanning and vectorization

Digitalization Errors

(1) Dangles: Lines that are not connected

(2) Overshoots: Overextended line

(3) Undershoots: Gap exists between two intersecting line

(4) Slivers: Gaps between two adjoining polygons

(5) Switchbacks, Knots, and Loops:

Digitized line with extra vertices and/or nodes due to unsteady hand of the digitizer

Coordinate systems

A reference system to represent the locations of geographic features

Each coordinate system is defined by:

➤ **Measurement framework**

Geographic: Spherical coordinates are measured from the earth's center

Planimetric: Earth's coordinates are projected onto a two-dimensional planar surface

➤ **Unit of measurement**

➤ Other measurement system properties such as a spheroid of reference, a datum, and projection parameters like one or more standard parallels, a central meridian, and possible shifts in the x- and y-directions

Representation of globe showing parallels and meridians lines

Coordinate systems

Geographic Coordinate System (GCS)

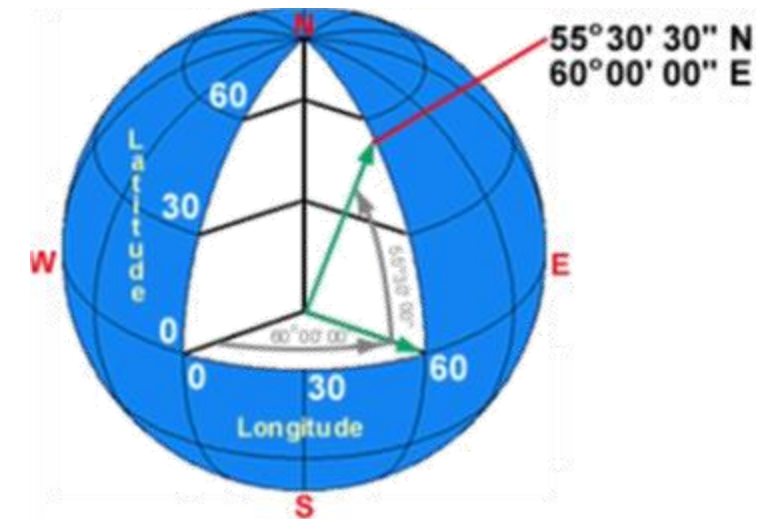

- Three-dimensional spherical surface to define locations on the earth
- A point is referenced by its longitude and latitude values that are the angles measured from the earth's center to a point on the earth's surface
- Vertical lines (north–south) are the lines of **longitude**, or **meridians**
- Horizontal lines (East–West) are the lines of equal **latitude**, or **parallels**

Coordinate systems

Geographic Coordinate System (GCS)

- The line of **latitude** midway between the poles is called the **equator**
- The **prime meridian (zero longitude)** is the longitude that passes through Greenwich, England
- The origin of the graticule (0, 0) is defined by where the equator and prime meridian intersect
- Coordinate value can be specified in **DMS**(degree, minutes, seconds) or **DD** (degree decimal)
- Directions can be specified using **E** (east), **W** (west), **N**(north), **S**(south) or by sign **plus** (+) or **minus** (-)

Coordinate systems

Projected Coordinate System (PCS)

- PCS is a reference system for transforming the spherical three-dimensional earth into two-dimensional planar surfaces
- Measuring features on a flat (map) surface
- PCS has constant lengths, angles, and areas across the two dimensions
- Locations are identified by planar x, y coordinates on a grid, with the origin at the center of the grid
- The two values are called the x-coordinate and y-coordinate

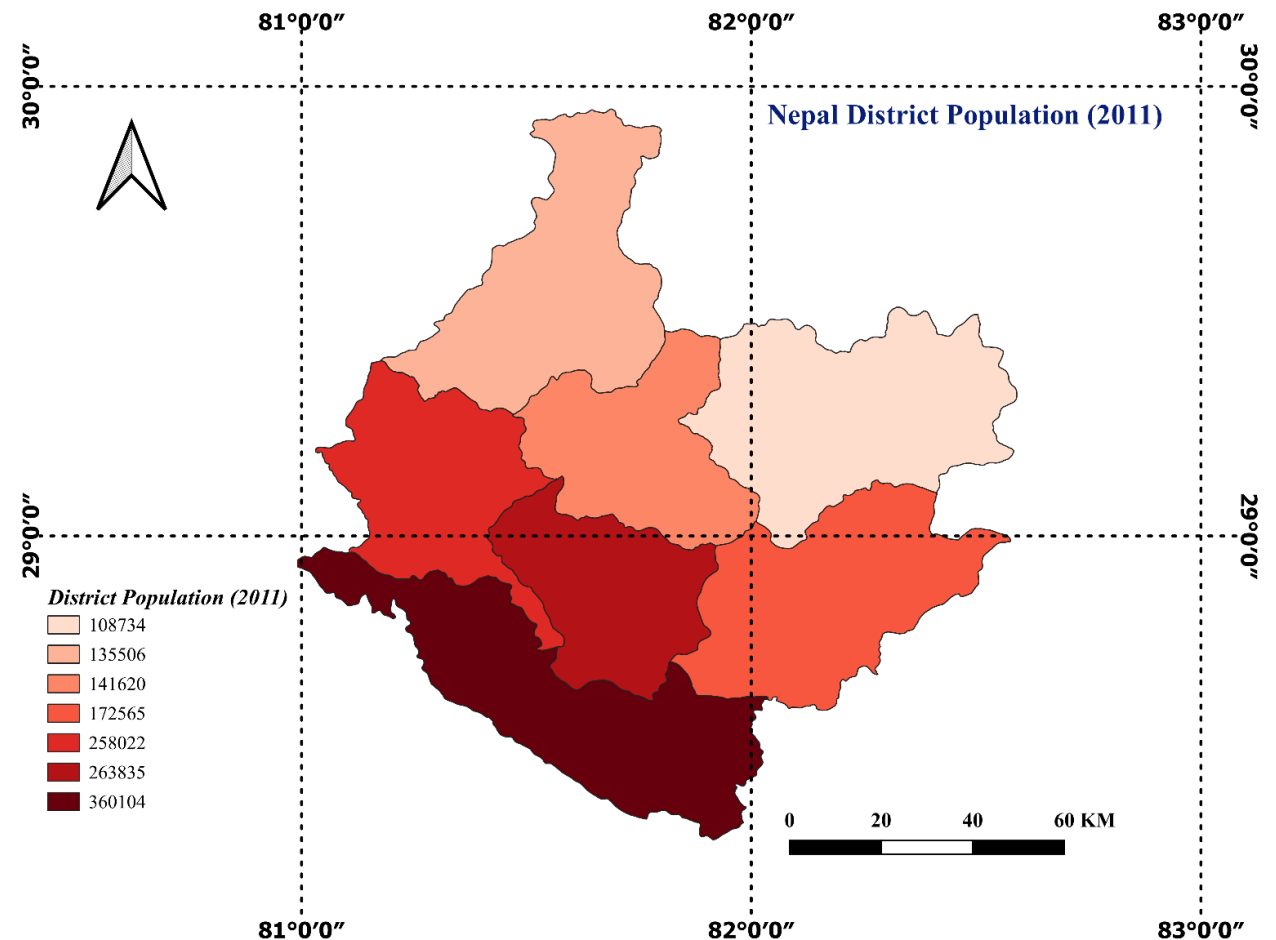

Map Production

Process of arranging Map elements on a sheet of paper

Properties

Applications of GIS

Mapping and monitoring Change dynamics

Source: Behera et al., 2017

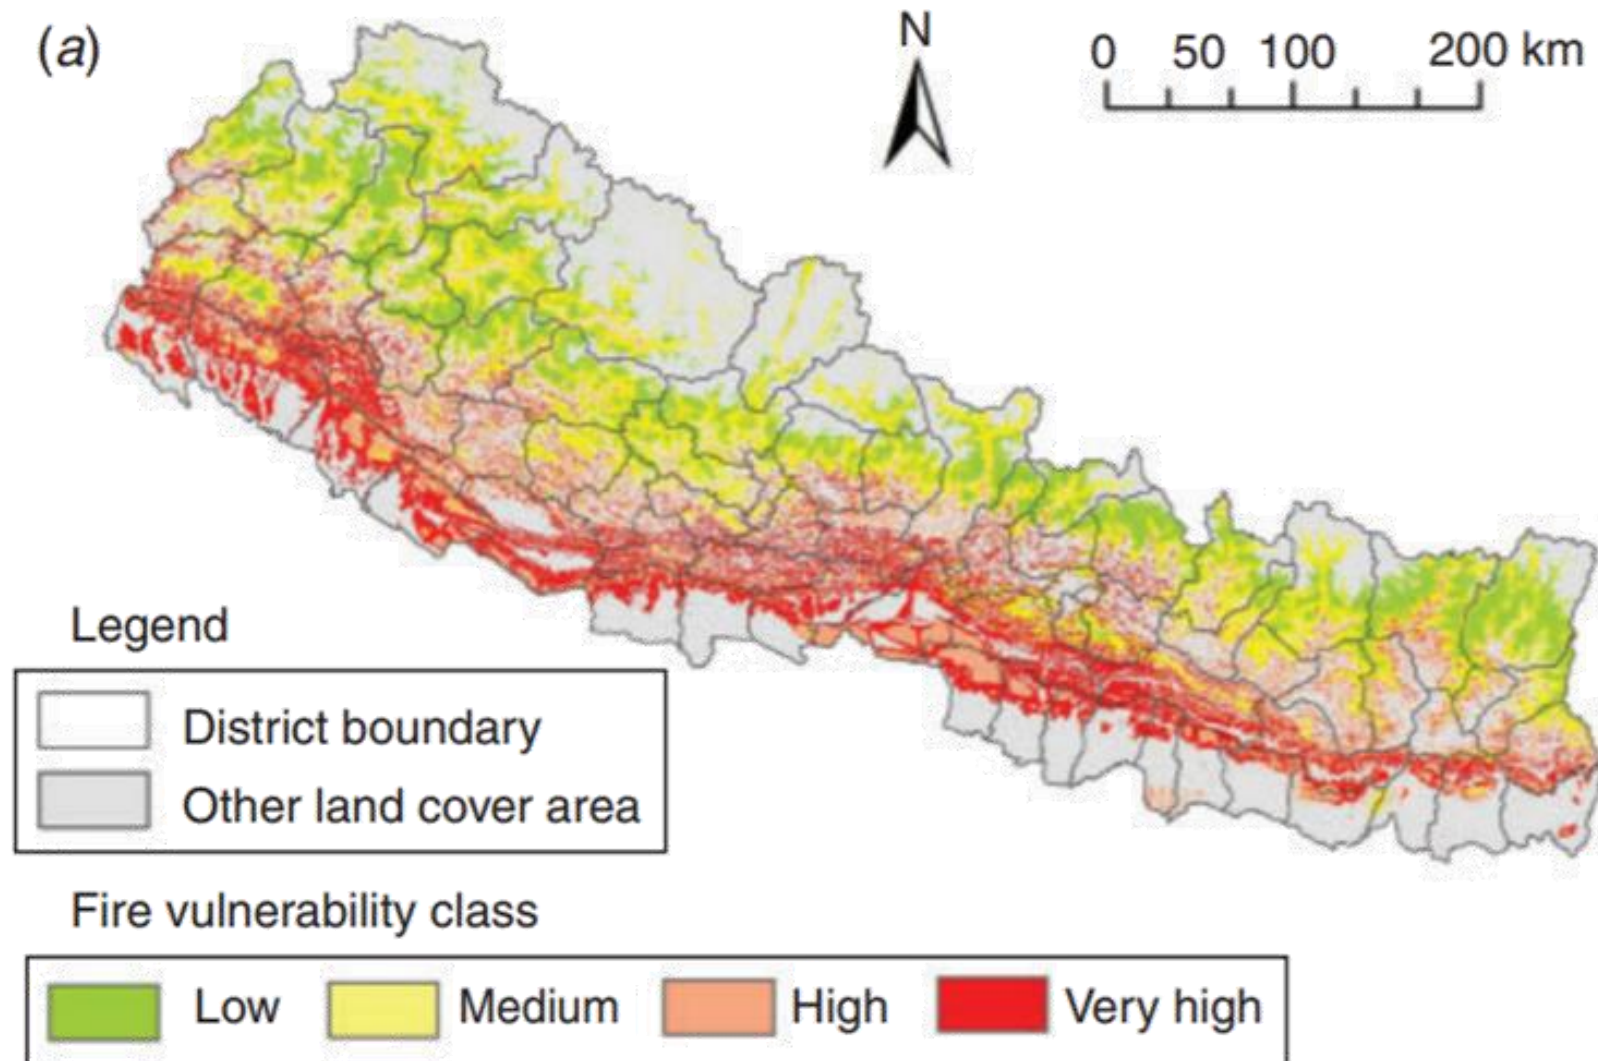

Applications of GIS

Fire risk modeling

Equation used for modelling

$$FRI = 10LCR + 6TR + 4(SDR + RDR) + 2(ER + SLR)$$

LCR: land cover rating
TR: temperature rating
SDR: settlement distance rating
RDR: road distance rating
ER: elevation rating
SLR :slope rating

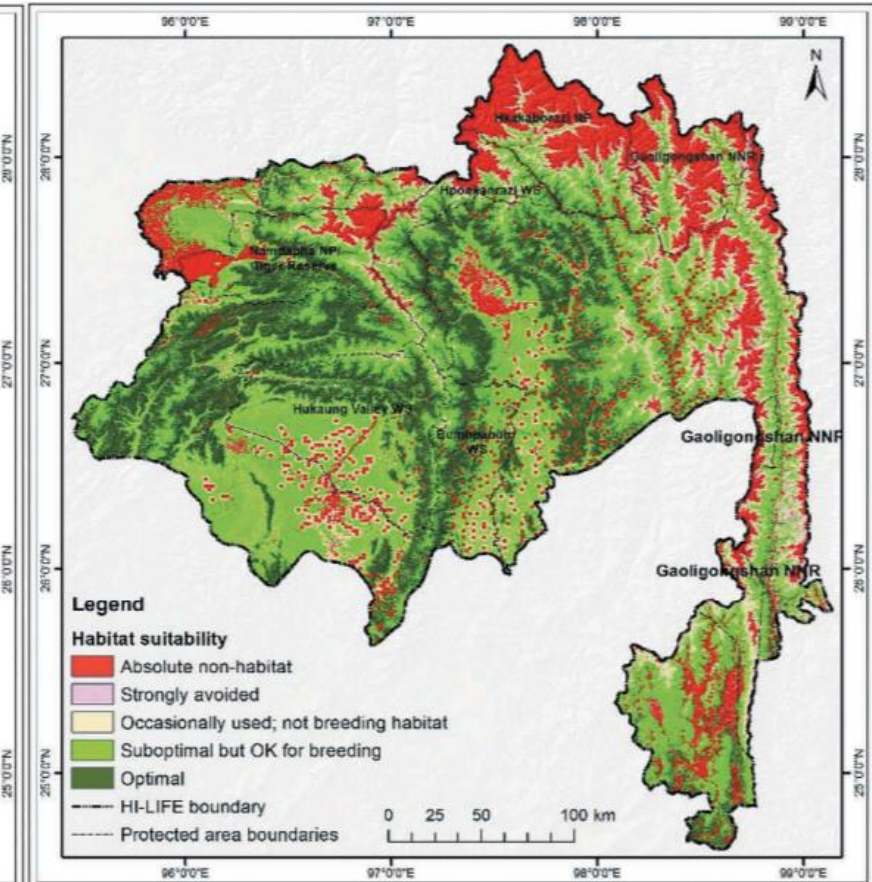

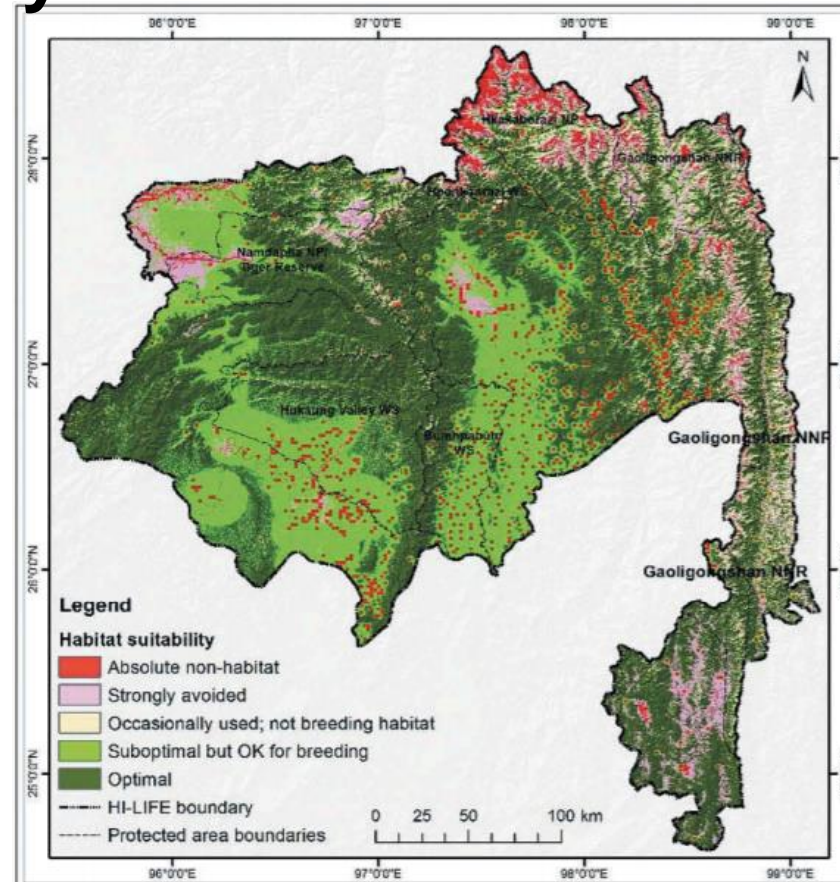

Source: *Matin et al., 2017*

Applications of GIS

Habitat Suitability Analysis

- Suitability scores assigned to each of the factors (e.g., land cover types, topographic position classes) paying particular attention to the suitability
- A numerical **weighting factor** was assigned to each thematic layer according to the relative importance of habitat suitability.

Himalayan black bear

Leaf deer

Applications of GIS

Risk & Hazard Analysis

Flood susceptibility analysis

(Markham river basin, New Guinea)

Equation used for modelling

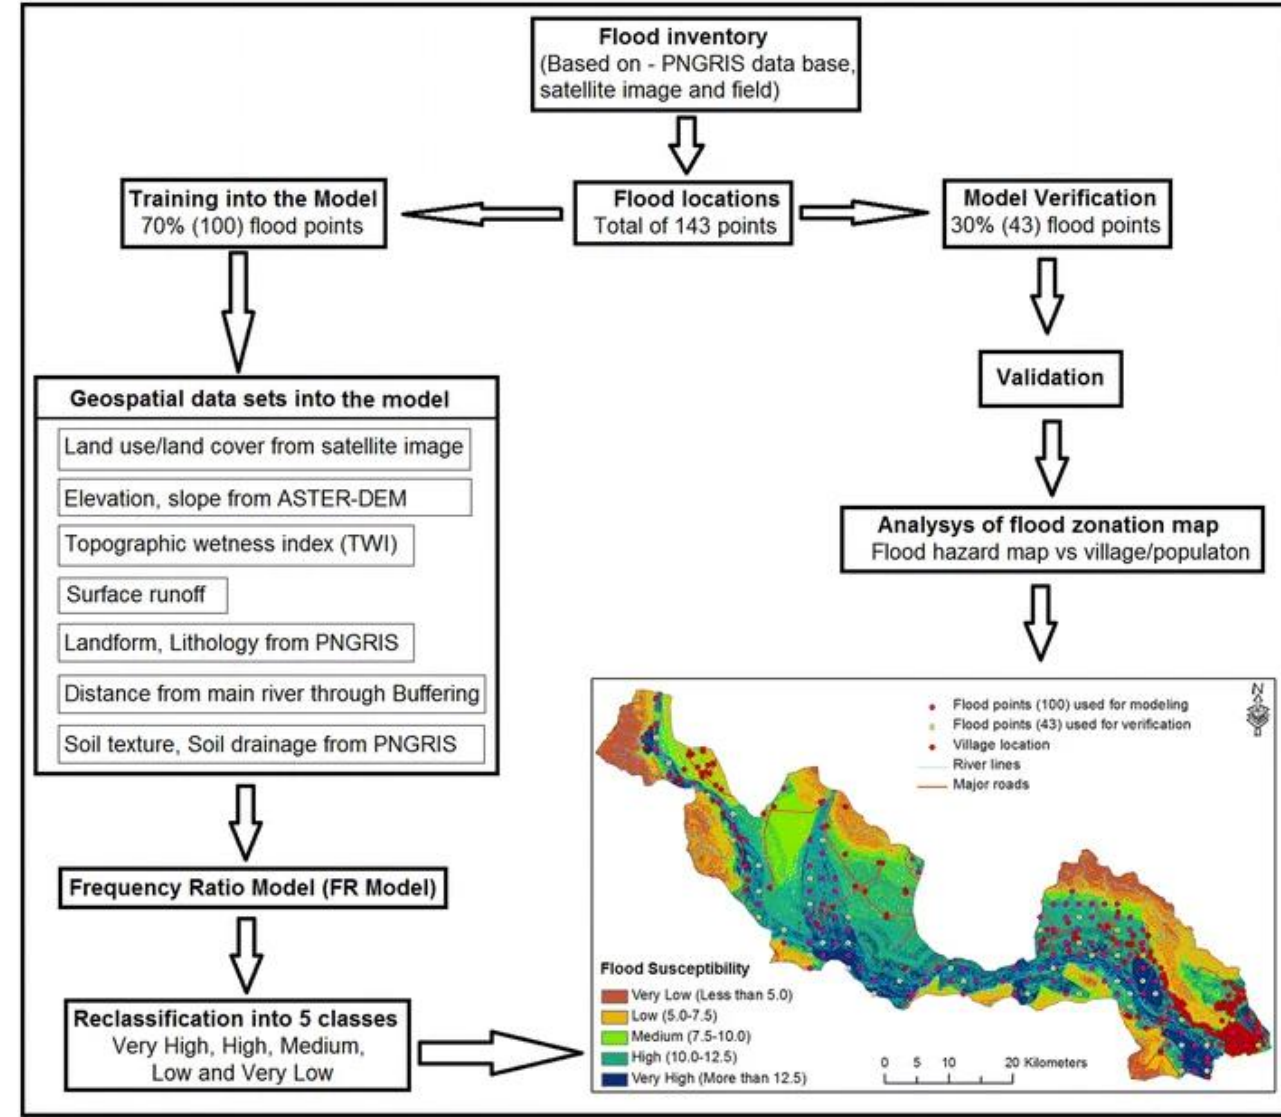

$$FSI = \sum FR,$$

where FSI is the flood susceptibility index and FR is the frequency ratio for each factor.

$$FR = (E/F)/(M/L),$$

where E is the number of flood episodes for each factor; F is the total number of flood episodes; M is the histogram of a class; L is the total histogram of the study area.

Source: Samanta et al., 2018

Risk & Hazard Analysis

Landslide susceptibility analysis

$$W_i = \ln \frac{\text{Density of landslide within a class of a factor}}{\text{Density of landslide within the study area}}$$
$$= \ln \frac{\frac{N_{pix}(S_i)}{N_{pix}(N_i)}}{\frac{\sum N_{pix}(S_i)}{\sum N_{pix}(N_i)}}$$

Where, W_i = Weight of a factor class;

$N_{pix}(S_i)$ = Number of pixel of landslide within class i ;

$N_{pix}(N_i)$ = Number of pixel of class i ;

$\sum N_{pix}(S_i)$ = Number of Pixel of landslide within the whole study area;

$\sum N_{pix}(N_i)$ = Number of pixel of the whole study area.

Class	LSI value	Description	Area in Square Kilometers	% Area of Map
1	-14.1493 to -9	Very Low	23.5449	1.81
2	-9 to -4	Low	330.9489	25.41
3	-4 to 0	Medium	602.1585	46.23
4	0 to 3	High	326.8251	25.09
5	3 to 8.5718	Very High	18.9441	1.45

Landslide Susceptibility Index Map

Landslide Susceptibility Class

Source: Bibek et al., 2015

Applications of GIS

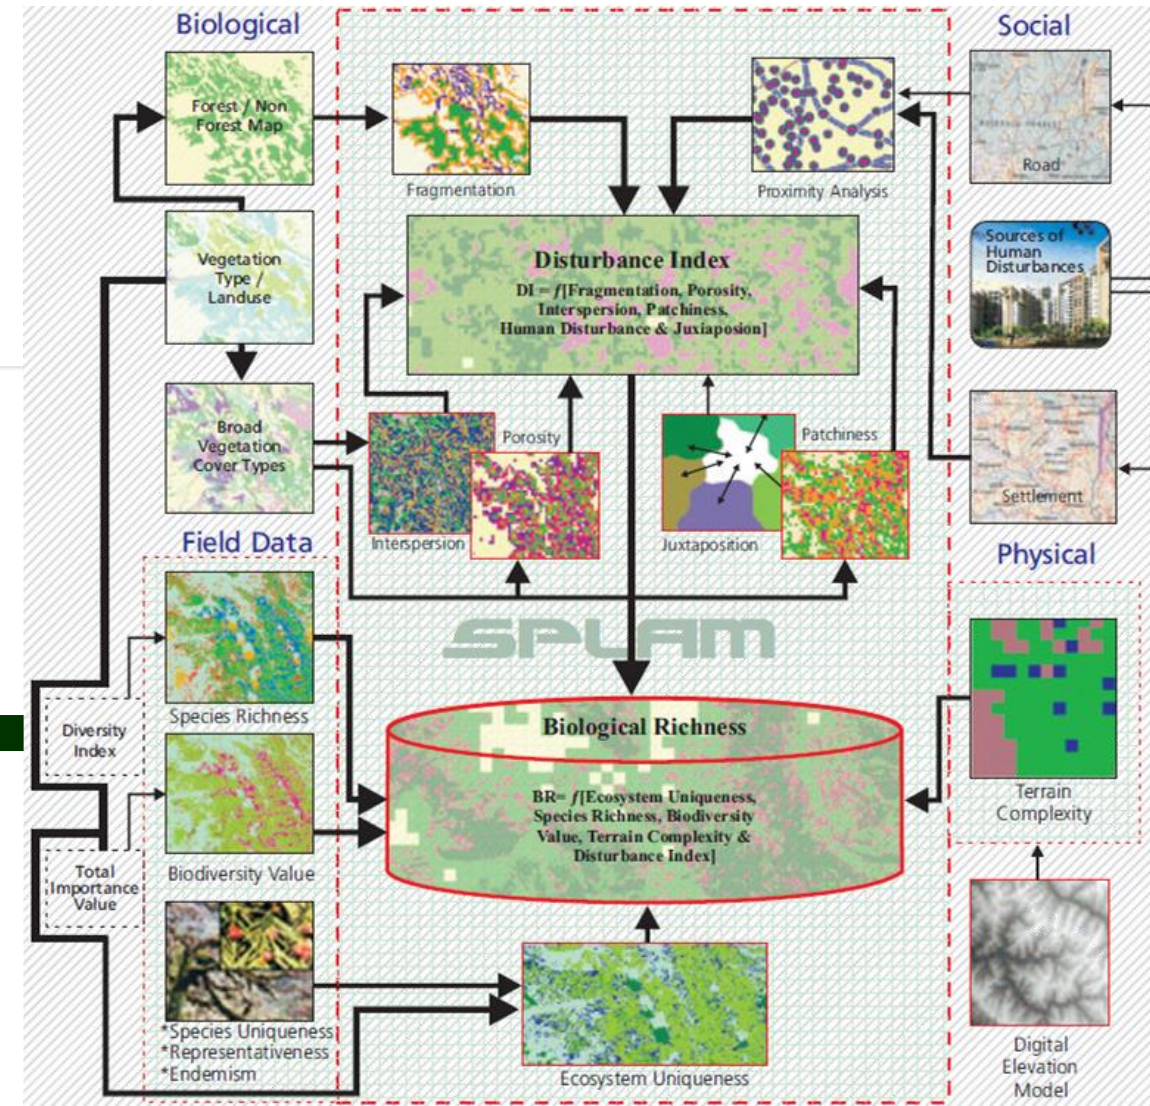

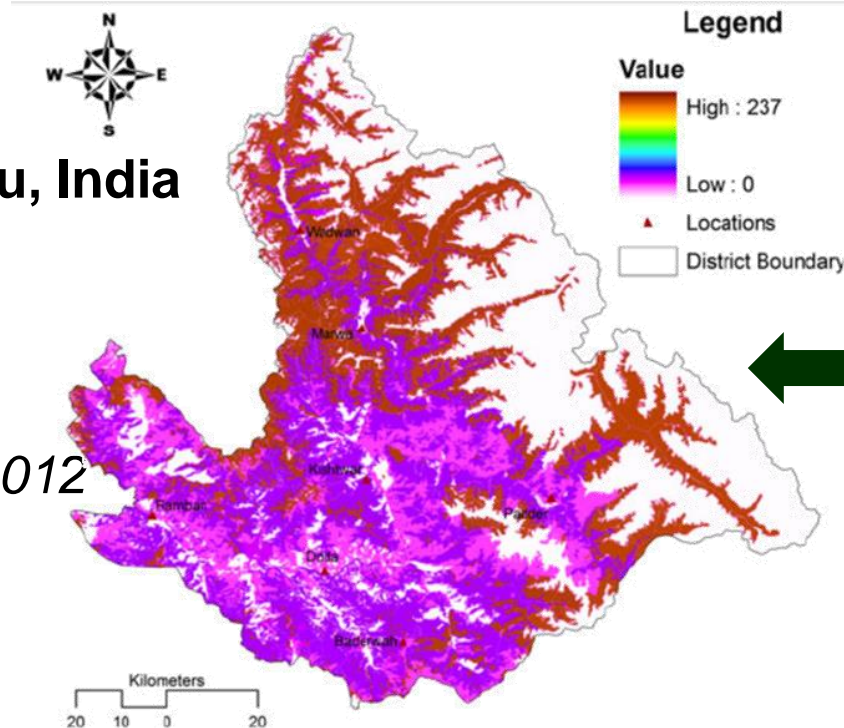

Biodiversity Analysis

$$BR = \sum_{i=1}^n (DI_i \times wt_{i1} + TC_i \times wt_{i2} + SR_i \times wt_{i3} + BV_i \times wt_{i4} + EU_i \times wt_{i5})$$

where BR = Biological Richness, DI = Disturbance Index, TC = Terrain Complexity, SR = Species Richness, BV = Biodiversity Value, EU = Ecosystem Uniqueness, and wt = Weights.

Doda district, Jammu, India
